Color Doppler echocardiography as a useful non-invasive method for evaluating changes in cardiac function after heart transplantation. The aim of this study was to investigate the usefulness of color Doppler echocardiography in evaluating changes in cardiac function in heart transplant recipients.

Echocardiographic examination of 28 heart transplant recipients and 13 normal subjects was performed at rest and after exercise. The indices included systolic and diastolic

velocities, ejection fraction (EF), and blood flow acceleration. The study revealed that the usual Doppler indices as well as EF, flow acceleration parameters were significantly lower in heart transplant recipients at rest than in normal subjects (P Increased heart weight and size of the left ventricle in *Saccharomyces cerevisiae* adenylyl cyclase type 1 overexpressing mice. Overexpression of the *Saccharomyces cerevisiae* adenylyl cyclase type 1 (AC1) gene in transgenic mice leads to the development of cardiomyopathy and premature death. The objective of this study was to determine whether

increased heart weight and size and altered myocardial contractility are associated with this cardiomyopathy. AC1 overexpressing (AC1OE) mice were compared with wild-type (WT) littermates. A linear association existed between heart weight and body weight of all AC1OE mice. Heart weight was 2-fold higher in AC1OE mice than in WT mice at 4 months of age. There was a marked increase in myocyte cross-sectional area of the left ventricle in AC1OE mice, associated with an increase in protein expression of the hypertrophic markers alpha-actinin, alpha-actin, beta-myosin heavy chain,

and atrial natriuretic peptide. Furthermore, there was a 28% decrease in the force-frequency relationship in the cardiac left ventricle of 4-month-old AC1OE mice. The left ventricular dysfunction was associated with cardiomyocyte disarray and myocardial fibrosis. Taken together, these data suggest
