Initial experience with a new image-guidance system in implant-based breast reconstruction. Intraoperative image-guidance can offer a new dimension to the surgeon in performing implant-based breast reconstruction. We present our initial experience using a new image-guidance system on 47 consecutive patients undergoing implant-based breast reconstruction performed by two fellowship-trained plastic surgeons. In this feasibility study, the authors evaluated the ability of this system to improve the surgeon's ability to place and rotate the breast implant during reconstruction. In addition, they found this system to be technically feasible and quite accurate. Using the Kinetic k-edge image-guidance system (Olympus), the authors guided their breast implant placement in the pre-pectoral pocket in 20 unilateral implant-based breast reconstructions. The authors' criteria for determining successful use of this system was as follows: 1) no inappropriate implant placement, 2) no need for intraoperative adjustment of the implant position, and 3) a rotational error of less than 10 degrees. Ten of 20 consecutive patients (50%) were able to implant the breast immediately after completion of the case, with no need for reoperation to reposition the implant. Fourteen patients (70%) successfully had their implants trimmed intraoperatively as needed to fit within the desired implant pocket. Only three patients (15%) had a surgical complication. The Kinetic k-edge image-guidance system offered a new and viable alternative to the surgeon's use of direct visualization in implant placement. This technique was found to be safe, technically feasible, and more accurate than previous techniques for implant placement in implant-based breast reconstruction. This technique was associated with less margin violation than was usually seen at our institution when using these older techniques. Cascading delaminations in patellofemoral surgery with a novel technique of repair. Medial patellofemoral ligament reconstruction has been shown to reduce patellofemoral instability in certain patient groups. Operative management of recurrent cases, however, is often difficult. Reconstruction of the medial patellofemoral ligament alone is often insufficient to provide complete stability, and the introduction of a lateral patellar subluxation mechanism may be indicated. This article describes a novel technique for the management of patellofemoral instability and recurrent patellar dislocation. This technique
